Descriptive Analysis of 1972 Cervical Corpectomy Patients and 30-Day Postoperative Outcomes

JAMES E. TOWNER, MD, YAN ICY LI, PhD, THOMAS A. PIETERS, MD, YAN MICHAEL LI, MD, PhD

Department of Neurosurgery, University of Rochester Medical Center, Rochester, New York

ABSTRACT

Background: There exists no large, multi-institutional analysis of patients undergoing cervical corpectomy for common degenerative spinal disease, including patient demographics and comorbidities as well as postoperative complications.

Methods: Using Current Procedural Terminology and International Classification of Diseases codes, 1972 patients who underwent a cervical corpectomy for degenerative spinal disease were identified from the American College of Surgeons National Surgical Quality Improvement Program data sets from 2012 to 2015. A descriptive analysis of the patients who underwent the procedure as well as 30-day outcomes and adverse events were collected. Multivariate logistic regression models were used to determine the effect of any preoperative factors identified from a univariate logistic regression analysis (variables with $P < .10$) of complications.

Results: The total complication rate, defined as major or minor adverse event, mortality, unplanned readmission, unplanned reoperation, or admission >30 days, was 13.28%. The percentage of patients who had ≥ 1 major or minor adverse events was 5.02%. Several factors commonly associated with an increased risk of perioperative complications, including smoking and diabetes, were found not to be independently associated with complications in this cohort.

Conclusions: This study is the largest analysis of cervical corpectomies. The results of the multivariate analysis provide guidance on risk factors associated with perioperative complications. These data could help develop risk-appropriate strategies for minimizing the effects of certain preoperative factors on perioperative complications.

Complications

Keywords: cervical corpectomy, vertebrectomy, ACS NSQIP, database, complication, descriptive analysis

INTRODUCTION

Cervical corpectomies are indicated for pathologies involving the ventral cervical spine, especially when the compressive lesion would not be addressed by completing a discectomy above and below the vertebral body.¹ Such conditions include degenerative spondylosis, tumors, ossifications of the posterior longitudinal ligament, and infectious processes, among other pathologies.² The largest published series describing cervical corpectomies have been single-institution series of several hundred patients.^{2–5} Although these reviews contain descriptions of risks and adverse events specific to cervical corpectomies, they fail to discuss in any detail the general adverse events associated with undergoing a surgical procedure, nor do they offer in-depth descriptions of patient comorbidities and their association with such adverse events. The purpose of this study is to examine a large, multi-institutional cohort of patients undergoing cervical cor-

pectomy for common degenerative spinal conditions. Using data from a large national database, we sought to provide an analysis of the patient population and adverse events among those undergoing cervical corpectomy.

MATERIALS AND METHODS

Data Source

The American College of Surgeons National Surgical Quality Improvement Program (ACS NSQIP) is a publicly available, prospectively collected, peer-controlled database created for the examination of 30-day, risk-adjusted surgical outcomes. Database entry is based on a review of patient records via clinically trained personnel. All patient information is de-identified in this nationally available database; thus, no Institutional Review Board evaluation of this study was required.

Table 1. ICD-9 codes with ≥ 10 patients and degenerative pathologies.

ICD-9 Code		Patients	Percentage
721.1	Cervical spondylosis with myelopathy	579	24.26
723	Spinal stenosis in cervical region	434	18.18
722	Displacement of cervical intervertebral disc without myelopathy	271	11.35
721	Cervical spondylosis without myelopathy	253	10.60
722.71	Intervertebral disc disorder with myelopathy, unspecified region	196	8.21
723.4	Brachial neuritis or radiculitis NOS	102	4.27
722.4	Degeneration of cervical intervertebral disc	88	3.69
723.1	Cervicalgia	30	1.26
722.91	Other and unspecified disc disorder	19	0.80
Total		1972	82.61

Patient Identification and Inclusion Criteria

We examined the ACS NSQIP data set from 2012 to 2015. Patients ages ≥ 18 years were identified using Current Procedural Terminology (CPT) codes. We included patients with the following CPT codes: 63081 (vertebral corpectomy, partial or complete, anterior approach with decompression of spinal cord and/or nerve root(s); cervical, single-segment) and 22554 (arthrodesis, anterior interbody technique, including minimal discectomy to prepare interspace [other than for decompression]; cervical below C2). All International Classification of Diseases, 9th revision (ICD-9) diagnosis codes were identified. In an attempt to generate a cohort representative of patients commonly receiving a cervical corpectomy, we excluded groups of ICD-9 diagnosis codes with fewer than 10 patients. Finally, we excluded all nondegenerative diagnoses so as to only include common degenerative conditions in this cohort. Table 1 lists the included ICD-9 diagnoses, as well as the number of patients with each associated diagnosis. The Figure illustrates the patient identification algorithm used to generate our cohort.

Preoperative Description

Table 2 lists the descriptive variables that were collected. The preoperative comorbidities that were collected are listed in Table 3.

Outcomes Definition

We examined 6 categories of outcomes: major complications, minor complications, reoperation, an admission lasting >30 days, readmission, and 30-day mortality. Major and minor complications were tracked from 2012 to 2015 and are listed in Table 4. Beginning in 2013, the NSQIP began tracking mortality, readmissions, and reoperation for the first 30 days after hospital discharge; therefore, data on these outcomes are only for 3 years (2013 through 2015).

Statistical Methods

Statistical analyses were performed using R version 3.4.1 (R Foundation for Statistical Computing). Risk factor analysis was completed in a stepwise fashion in order to illuminate true associations and limit the identification of spurious associations. All preoperative factors were first analyzed with a univariate logistic regression model to identify preoperative factors significantly associated with outcomes. Statistical significance was set a priori at an α of 0.10 for the univariate logistic regression model. All variables were noted to have clinical plausibility for being associated with outcomes being investigated, so they were retained for further analysis. Next, these identified variables were subjected to a multivariate logistic regression

model to determine which preoperative variables remained statistically significantly associated with our outcome measures of interest. Statistical significance was set a priori at an α of 0.05 for the multivariate logistic regression model.

RESULTS

Our search identified 1972 adult patients undergoing a cervical corpectomy for common degenerative spinal diagnoses. Tables 2 and 3 include descriptive statistics of the patient characteristics and preoperative factors, respectively. Table 4 lists the rates of adverse events. The total complication rate, defined as major or minor adverse event, mortality, unplanned readmission, unplanned reoperation, or an admission lasting >30 days, was 13.28%. The percentage of patients who had ≥ 1 major or minor adverse events was 5.02%. The most common major adverse event was unplanned reintubation, occurring in 1.12% of patients. The

Steroid use for chronic condition	12.40 (1.88–76.52)	.005
>10% loss of body weight	41.53 (0.95–883.38)	.031

Abbreviations: ASAP, American Society of Anesthesiology Physical Status Classification; CI, confidence interval; COPD, chronic obstructive pulmonary disease; OR, odds ratio.

rates of unplanned reoperation and unplanned readmission were 2.59% (51 patients) and 4.01% (79 patients), respectively.

Table 5 lists the preoperative factors associated with categories of adverse events (major adverse events, readmission, and mortality) from the multivariate analyses. For both mortality and major adverse events, the highest odds ratio (OR) was for patients with >10% loss of body weight in the past 6 months, OR 41.534 ($P = 0.031$) and OR 11.153 ($P = 0.027$), respectively. For readmission, the highest OR was associated with any wound classification besides clean (OR, 15.138; $P < .001$).

DISCUSSION

Previously published complication rates for cervical corpectomy range from 11% to 36%, with mortality ranging from 0 to 2.8%.^{2–5} The mortality rate of 0.3% in our cohort is on the lower end of the range identified by previously published reports.^{2–4} The total 30-day complication rate, defined as any major or minor adverse events, mortality, unplanned reoperation, unplanned readmission, or an admission lasting >30 days, is 13.28% in our cohort, also lower than previously published single-institution, retrospective reviews of cervical corpectomies, which reported rates between 20.8% and 22.7%.^{2,4} The categories and subcategories of complications in these previously published reviews included many additional complications that are specific to anterior cervical surgery, such as C5 nerve root palsy, dysphagia, recurrent laryngeal nerve injury, and cerebrospinal fluid leak. However, these previous reports failed to examine many clinically meaningful complications that we incor-

porated into our findings. These include the incidence of relatively common issues, such as the need for blood transfusion (1.57%) and urinary tract infections (0.46%), as well as rarer adverse events that may not occur with enough frequency to be reported in smaller series, like stroke (0.10%), renal insufficiency (0.05%), and acute renal failure (0.05%). Additionally, the indications for surgery in our patient cohort are much more homogenous (i.e., degenerative spinal disease) compared with the prior reports, which include such diverse indications as traumatic injuries, malignancy, and infections. We feel our findings are more applicable to patients with degenerative conditions.^{3,4} It is important to note that our series includes patients who had multilevel cervical corpectomies, which may overestimate the risk profile for single-level corpectomies and may underestimate the risk profile for multilevel cervical corpectomies.

The results of the analysis reveal some interesting associations between preoperative factors and perioperative complications. Perhaps the most surprising finding was that smoking status was not found to be associated with any of the complication categories we assessed, although severe COPD was associated with both major adverse events and 30-day mortality on multivariate analysis. Many perioperative complications have been previously associated with smoking, including impaired wound healing, infections, unplanned intubations, and the need for mechanical ventilation.^{5,6} However, in a previous study examining smoking status in patients undergoing anterior cervical corpectomy there was only a trend towards an increase in infectious complications in smokers that did not reach statistical significance.⁵ Further, in a prior NSQIP study of posterior cervical spine surgery, smoking was not found to be associated with risk of infection.⁷ We hypothesize that perhaps the smoking cohort included light or occasional smokers who may be at lower risk for perioperative complications compared with heavy smokers, for which having COPD may have functioned as a surrogate marker. Moreover, smoking may not have been found to be associated with infection in this series because the actual incidence of infections was quite low, at 0.61% (12 of 1972 patients), limiting our ability to statistically determine relationships for this complication in our data set. Previous reports of infection rates range from 0 to 4.3%.^{2–4}

Greater than 10% total body weight loss in the 6 months preceding surgery was found to be associated with major adverse events and mortality. The etiology for the weight loss was not likely due to underlying malignancy, because patients with a diagnosis of malignancy were excluded from this analysis. Therefore, it is a reflection of other underlying comorbidities and/or nutritional deficiency. This potentially modifiable risk factor warrants further study because interventions such as nutrition counseling or diet modification (e.g., high-protein preoperative diet) would be relatively easy to institute.

Data input into ACS NSQIP is done by a trained surgical clinical reviewer at each site with interrater reliability audits conducted at selected sites in order to ensure accurate data entry.⁸ Despite the rigorous steps to ensure valid data, there are limitations to the collected data sets. First, cases are identified based on CPT codes, which introduces coding errors as a cause of misidentifying cases. Because of the large number of operations tracked, the variables must be generic in order to streamline entry. Preventative endeavors, such as perioperative antibiotics or venous thromboembolic prophylaxis, are not recorded, and it is therefore impossible to estimate the effect such measures could have on complication rates. This likely results in an underestimation of the risk of some complications when such preventative efforts are not made.⁸ Also, although there are more than 400 hospitals that contribute data and there is likely less bias than in single-institution studies, the ACS NSQIP data set does not represent a validated nationally representative sample.⁸

As alluded to previously, one major limitation of our analysis is that there are many complications unique to cervical spine surgery that are not captured in the ACS NSQIP database. One of the most common complications is postoperative dysphagia, with rates ranging from 0% to 58%.⁹ C5 nerve root palsy, manifesting as deltoid and/or biceps brachii weakness, is an early postoperative complication, with 2 meta-analyses finding an incidence of 7.5% for anterior cervical corpectomy and fusion.^{10,11} Other potential complications unique to anterior cervical approaches not reported in the ACS NSQIP data set include perioperative complications, like recurrent laryngeal nerve injury, cerebrospinal fluid leak, and sympathetic chain

disruption, as well as long-term morbidity, such as pseudarthrosis rates and adjacent-level stenosis.

Once a condition of the cervical spine has been determined to require operative management, surgical planning must include choosing the approach (anterior, posterior, or combined), the procedure, and how to stabilize the cervical spine, if needed. In the case of a corpectomy, the cervical spine must be reconstructed, which can be completed with an autograft or allograft, with or without additional instrumentation.⁴ Our database study does not provide insight into these details, for which we refer readers to prior studies regarding information on the type of construct used for the fusion, as well as studies comparing cervical corpectomies with other surgical approaches.^{9,12–19}

CONCLUSION

Our study is the largest analysis of cervical corpectomies for common degenerative cervical spinal diseases, adding evidence regarding the general risk profile, including for several adverse outcomes that have not been previously examined. These data are important for the consideration of patient selection and patient counseling prior to surgery. They could additionally help develop risk-specific strategies for minimizing the effects of certain preoperative factors on perioperative complications; for instance, early ambulation or institution of chemical venous thromboprophylaxis for lowering deep venous thrombosis incidence in high-risk patients; aggressive and vigilant wound care; and nutrition modification in high-risk patients. Further development of risk scores or risk calculators could translate these data into a convenient clinical device for guiding decision-making.
